ABSTRACT
Supplier selection is one of the most important activities of purchasing departments. This importance is increased even more by new strategies in a supply chain, because of the key role suppliers perform in terms of quality, costs and services which affect the outcome in the buyer’s company. Supplier selection is a multiple criteria decision making problem in which the objectives are not equally important. In practice, vagueness and imprecision of the goals, constraints and parameters in this problem make the decision making complicated. Simultaneously, in this model, vagueness of input data and varying importance of criteria are considered. In real cases, where Decision- Makers (DMs) face up to uncertain data and situations, the proposed model can help DMs to find out the appropriate ordering from each supplier, and allows purchasing manager(s) to manage supply chain performance on cost, quality, on time delivery, etc. An additive weighted model is presented for fuzzy multi objective supplier selection problem with fuzzy weights. The model is explained by an illustrative example.

1. Introduction
In most industries the cost of raw materials and component parts constitutes the main cost of a product, such that in some cases it can account for up to 70% [9]. Thus the purchasing department can play a key role in an organization’s efficiency and effectiveness because of the key role of a supplier’s performance on cost, quality, delivery and service in achieving the objectives of a supply chain. Supplier selection is a multiple criteria decision-making (MCDM) problem which is affected by several conflicting factors. Consequently a purchasing manager must analyze the trade off among the several criteria. Multiple criteria decision-making techniques support the decision makers in evaluating a set of alternatives. Depending upon the purchasing situations, criteria have varying importance and there is a need to weight criteria [7]. In a real situation for a supplier selection problem, many input information are not known precisely. At the time of making decisions, the value of many criteria and constraints are expressed in vague terms such as “very high in quality” or “low in price”. Deterministic models cannot easily take this vagueness into account. In these cases the theory of fuzzy sets is one of the best tools for handling uncertainty. Fuzzy set theories are employed due to the presence of vagueness and imprecision of information in the supplier selection problem. In this paper, for the first time, a fuzzy multi objective model has been developed for the supplier selection problem, in which different fuzzy weights can be considered for various objectives.

2. Literature Review
The literature in this area discusses either the criteria or the methods of supplier selection. Dickson [6] firstly identified and analyzed the importance of 23 criteria for supplier selection based on a survey of purchasing managers. He showed that quality is the most important criterion followed by delivery and performance history. Weber et al. [27] reviewed 74 articles discussing supplier selection criteria, and showed that net price is
the most important criterion for supplier selection. They also concluded that supplier selection is a multi-criteria problem and the priority of criteria depends on each purchasing situation. Rao and Kiser [21] and Bache et al [1] identified, respectively, 60 and 51 criteria for supplier selection. Gaballa [8] is the first author who applied mathematical programming to supplier selection in a real case. He used mixed integer programming to minimize the total discounted price of allocated items to the suppliers. Bender et al. [3] formulated a single objective, mixed integer programming to minimize the sum of purchasing, transportation and inventory costs by considering multiple items, multiple time periods, vendors’ quality, delivery and capacity. Pan [20] used a single objective linear programming model to choose the best suppliers. This model minimizes total cost, and quality and service are considered as constraints. Sharma et al. [23] proposed a non-linear, mixed integer, goal-programming model for supplier selection. They considered price, quality, delivery and service in their model, in which all criteria are considered as goals. Weber and Current [27] used a multi-objective approach to systematically analyse the trade-offs between conflicting criteria in supplier selection problems. Three objectives are formulated to minimize aggregate purchasing cost, number of late deliveries and rejected items.

Ghodsypour and O’Brien [10] developed a decision support system (DSS) for reducing the number of suppliers according to supply-based optimization strategy. They used an integrated analytical hierarchy process (AHP) with mixed-integer programming and considered suppliers’ capacity constraint and the buyers’ limitations on budget and quality etc. in their DSS. Ghodsypour and O’Brien [11] developed an integrated AHP and linear programming model to consider both qualitative and quantitative factors in purchasing activity. Karpak et al. [14] used a goal programming model to minimize costs and maximize delivery reliability and quality in supplier selection when assigning the order quantities to each supplier. Degreave and Roodhooft [5] developed a total cost approach with mathematical programming to treat supplier selection using activity based cost information. Ghodsypour and O’Brien [12] developed a mixed-integer non-linear programming approach to minimize total cost of logistics, including net price, storage, ordering costs and transportation in supplier selection.

In the literature, little attention has been paid to develop supplier selection models to deal with imprecise information and vagueness of the problem. In order to deal with incomplete and qualitative data, simple linear weighting models have been adapted to handle uncertainty in decision-making related to unstructured purchasing situations [24]. Narasimhan[18] and Nydick and Hill [19] proposed the use of AHP to deal with imprecision in supplier choice using linear weighting models for finding the supplier with the highest overall rating. Morlacchi[16] developed a model that combines the use of fuzzy set theory (FST) with analytic hierarchy process (AHP) and implements it to evaluate small suppliers in the engineering and machine sectors. In the literature, relatively scarce attention has been paid to develop effective supplier selection models for the supplier selection problem simultaneously trying to deal with: unstructured relevant information, quanti/quantitative and/or absent/imprecise input data and the basic problem of weights (importance of evaluative criteria) assessment. Usually, these aspects have been analyzed one at a time by each model.

No authors discussed the fuzzy multiple criteria decision making methods to the problem of supplier selection with various important criteria, the current study addresses this research gap by providing a quantitative model. This fuzzy model enables the purchasing managers not only to consider the imprecision of information but also take the limitations of buyer and supplier into account to calculate the order quantity assigned to each supplier. The paper is organized as follows: in section 3 the fuzzy multiobjective model and its crisp formulation for the supplier selection problem is presented in which the objectives are not equally important and have different weights. First, a general linear multi-objective formulation for this problem is considered and then some definitions and appropriate approach for solving this decision making problem are discussed. Section 4 presents the numerical example and explains the results. Finally, the concluding remarks are presented in section 5.

3. The Multi Objective Supplier Selection Model

A general multi objective model for the supplier selection problem can be stated as follows [27,12]:

\[
\begin{align*}
\text{Min } & Z_1, Z_2 \ldots Z_q \\
\text{Max } & Z_p+1, Z_{q+2} \ldots Z_q
\end{align*}
\]

Subject to:

\[
x \in X_d, \ X_d=\{x/g(x) \leq b, \ i=1,2, \ldots,m\}
\]

in which the \( Z_1, Z_2, \ldots Z_q \) are the negative objectives or criteria like cost, late delivery, etc. and \( Z_{p+1}, Z_{q+2} \ldots Z_q \) are the positive objectives or criteria such as quality, on time delivery, after sale service and so on. \( X_d \) is the set of feasible solutions which satisfy the constraint such as buyer demand, supplier capacity, etc. A typical linear model for supplier selection problems is as follows[20,27]:

\[
\text{Min } Z_i = \sum_{j=1}^{n} P_i X_{ij}
\]
Max Z\(=\sum_{i=1}^{n} F_i X_i\) \hspace{1cm} (5)

Max Z\(=\sum_{i=1}^{n} S_i X_i\) \hspace{1cm} (6)

Subject to:
\[
\sum_{i=1}^{n} x_i \geq D \hspace{1cm} (7)
\]
\[
x_i \leq C_i \quad i=1, 2, ... n \hspace{1cm} (8)
\]
\[
x_i \geq 0 \quad i=1, 2, ... n \hspace{1cm} (9)
\]

where:
- \(D\) = demand over period
- \(x_i\) = the number of units purchased from the \(i\)th supplier
- \(P_i\) = per unit net purchase cost from supplier \(i\)
- \(C_i\) = capacity of \(i\)th supplier
- \(F_i\) = percentage of quality level of \(i\)th supplier
- \(S_i\) = percentage of service level of \(i\)th supplier
- \(n\) = number of suppliers

Three objective functions - net price (4), quality (5), and service (6) - are formulated to minimize total monetary cost, maximize total quality and service level of purchased items. Constraint (7) ensures that demand is satisfied. Constraint set (8) means that order quantity of each supplier should be equal or less than its capacity and constraint set (9) prohibits negative orders.

In a real case, decision makers do not have exact and complete information related to decision criteria and constraints. For supplier selection problems the collected data does not behave crisply and they are typically fuzzy in nature. A fuzzy multi objective model is developed to deal with the problem. Before presenting the fuzzy model, some definitions and notation should be discussed.

3.1. Definitions
Fuzzy set theory uses linguistic variables rather than quantitative variables to represent imprecise concepts. Linguistic variables analyse the vagueness of human language.

**Fuzzy set:** Let \(X\) be a universe of discourse, \(A\) is a fuzzy subset of \(X\) if for all \(x \in X\), there is a number \(\mu_A\) (\(x\)) \(\in [0,1]\) assigned to represent the membership of \(x\) to \(A\), and \(\mu_A\) (\(x\)) is called the membership function of \(A\).

**Fuzzy number:** A fuzzy number \(A\) is a normal and convex subset of \(X\). Normality implies
\[
\exists x \in R \nexists \mu_A(x) = 1.
\]
Convexity implies
\[
\forall x_1 \in X, x_2 \in X, \forall \alpha \in [0,1] \mu_A(\alpha x_1 + (1-\alpha) x_2) \geq \min \mu_A(x_1), \min \mu_A(x_2).
\]

**Fuzzy decision:** A fuzzy decision is defined in an analogy to non-fuzzy environments “as the selection of activities which simultaneously satisfy objective functions and constraints” in fuzzy set theory the intersection of sets normally corresponds to the logical “and”. The “decision” in a fuzzy environment can therefore be viewed as the intersection of fuzzy constraints and fuzzy objective functions \([29]\).

Constructing fuzzy decision model depends upon the selection of operators. For fuzzy decision making, the selection of appropriate operators is very important. Zimmermann \([30]\) classified eight important criteria that may be helpful for selecting the appropriate operators in fuzzy decisions. In the next section, the appropriate operator related to the fuzzy supplier selection problem is discussed.

3.2. The Fuzzy Supplier Selection Model
In this section, first the general multi objective model for supplier selection is presented and then appropriate operators for this decision making problem are discussed.

A general linear multi objective model can be presented as:

Find a vector \(x\) written in the transformed form \(x^{T} = [x_1, x_2, .., x_n]\) which minimizes objective functions \(Z_k\) and maximizes objective function \(Z_l\):

\[
\begin{align*}
\text{Min } Z_k &\equiv \sum_{i=1}^{n} c_{kj}x_j \quad k=1, 2... p \\
\text{Max } Z_l &\equiv \sum_{i=1}^{n} c_{lj}x_j \quad l=p+1, p+2... q
\end{align*}
\]

with constraints:

\[
x \in X, \quad X_i = \{x \mid g(x) \leq b_i, \quad i=1,2,..m, \quad x \geq 0\}
\]

where \(c_{ij}, c_{ij}, a_{ij}\) and \(b_i\) are crisp or fuzzy values. Zimmermann \([29]\) has solved the problem (10), (11) and (12) by using fuzzy linear programming. He formulated the fuzzy linear program by separating every objective function \(Z_i\) into its maximum \(Z_i^+\) and minimum \(Z_i^-\) value by solving:

\[
\begin{align*}
Z_i^+ & =\text{Max } Z_i(x), \quad x \in X, \quad Z_i^- = \text{Min } Z_i(x), \quad x \in X
\end{align*}
\]

\[
\begin{align*}
Z_i^+ & =\text{Max } Z_i(x), \quad x \in X, \quad Z_i^- = \text{Min } Z_i(x), \quad x \in X
\end{align*}
\]

\[
\begin{align*}
Z_i^+ & =\text{Max } Z_i(x), \quad x \in X, \quad Z_i^- = \text{Min } Z_i(x), \quad x \in X
\end{align*}
\]

\[
\begin{align*}
Z_i^+ & =\text{Max } Z_i(x), \quad x \in X, \quad Z_i^- = \text{Min } Z_i(x), \quad x \in X
\end{align*}
\]

\[
\begin{align*}
Z_i^+ & =\text{Max } Z_i(x), \quad x \in X, \quad Z_i^- = \text{Min } Z_i(x), \quad x \in X
\end{align*}
\]

\[
\begin{align*}
Z_i^+ & =\text{Max } Z_i(x), \quad x \in X, \quad Z_i^- = \text{Min } Z_i(x), \quad x \in X
\end{align*}
\]
Since for every objective function $Z_k$, its value changes linearly from $Z_k^-$ to $Z_k^+$, it may be considered as a fuzzy number with the linear membership function $\mu_j (z)$ as shown in Figure 1. It was shown that a linear programming problem (10), (11) and (12) with fuzzy goal and fuzzy constraints may be presented as follows:

Find a vector $x$ to satisfy:

$$\tilde{Z}_k (x) = \sum_{j=1}^{n} c_{kj} x_j \leq Z_k^0, \quad k=1, 2... p \quad (15)$$

$$\tilde{Z}_l (x) = \sum_{j=1}^{n} c_{lj} x_j \geq Z_l^0, \quad l=p+1, p+2... q \quad (16)$$

subject to:

$$\tilde{g}_i (x) = \sum_{j=1}^{n} a_{ij} x_j \leq b_i, \quad i=1,2...h \quad (17)$$

$$g_i (x) = \sum_{j=1}^{n} a_{pj} x_j \leq b_p, \quad p=h+1,...m \quad (18)$$

$$x \geq 0 \quad (19)$$

In this model, the sign $\sim$ indicates the fuzzy environment. The symbol $\leq$ in the constraints set denotes the fuzzified version of $\leq$ and has linguistic interpretation “essentially smaller than or equal to” and $Z_k^+$ is the upper bound of minimizing goal $Z_k$ and $Z_k^-$ is the lower bound of maximizing goal $l$ (aspiration levels that the decision maker wants to reach). Assuming that membership functions, based on preference or satisfaction are linear, the linear membership for minimization goals ($Z_k$) and maximization goals ($Z_l$) are given as follows:

$$\mu_k (x) = \begin{cases} Z_k - Z_k(x)/Z_k^0 - Z_k^- & \text{for } Z_k \leq Z_k^- \quad (k=1, 2... p) \\ 1 & \text{for } Z_k \leq Z_k \leq Z_k^0 \\ 0 & \text{for } Z_k \geq Z_k^0 \end{cases} \quad (20)$$

$$\mu_l (x) = \begin{cases} Z_l^- - Z_l(x)/(Z_l^- - Z_l) & \text{for } Z_l \leq Z_l^- \quad (l=p+1,p+2... q) \\ 1 & \text{for } Z_l \leq Z_l \leq Z_l^0 \\ 0 & \text{for } Z_l \geq Z_l^0 \end{cases} \quad (21)$$

The linear membership function for the fuzzy constraints is given as:

$$\mu_i (x) = \begin{cases} 1 & \text{for } g_i(x) \leq b_i, \quad (i=1, 2... h) \\ 1-(g_i(x)-b_i)/d_i & \text{for } b_i \leq g_i(x) \leq b_i+d_i \\ 0 & \text{for } g_i(x) \geq b_i+d_i \end{cases} \quad (22)$$

The $d_i$ is subjectively chosen constants expressing the limit of the admissible violation of the $i$th inequalities constraints (tolerance interval). In the next section some important fuzzy decision making operators will be presented.

3.3. Decision Making Operators

First, the max-min operator is discussed, which was used by Zimmermann [29,30] and for fuzzy multi objective problems. Then, the convex (weighted additive) operator is stated that enables the decision makers (DMs) to assign different weights to various criteria.

In fuzzy programming modeling, using Zimmermann’s approach, a fuzzy solution is given by the intersection of all the fuzzy sets representing either fuzzy objective or fuzzy constraints. The fuzzy solution for all fuzzy objectives and h fuzzy constraints may be given as:

$$\mu_{D_p} (x) = \left\{ \bigcup_{i=1}^{q} \mu_{g_i} (x) \right\} \bigcap \left\{ \bigcup_{i=1}^{h} \mu_{b_i} (x) \right\} \quad (23)$$

The optimal solution($x^*$) is given by:

$$\mu_{D_p} (x^*) = \max_{x \in X_p} \min_{x \in X_c} \left( \mu_{g_i} (x), \mu_{b_i} (x) \right) \quad (24)$$

In this solution the relationship between constraints and objective functions in a fuzzy environment is fully symmetric [29]. In other words, in this definition of the fuzzy decision, there is no difference between the fuzzy goals and fuzzy constraints. Therefore, depending on the supplier selection problem, situations in which fuzzy goals and fuzzy constraints have unequal importance to DMs and other patterns, as their confluence of objectives and constraints, should be considered.

The weighted additive model can handle this problem which is described as follows. The weighted additive model is widely used in vector objective optimization problems; the basic concept is to use a single utility function to express the overall preference of DMs to draw out the relative importance of criteria [15].

In this case, a linear weighted utility function is obtained by multiplying each membership function of fuzzy goals by their corresponding weights and then adding the results together.

The convex fuzzy model proposed by Bellman and Zadeh [2], Sakawa [22] and the weighted additive model, Tiwari et al. [25] is:
\[ \mu_D(X) = \sum_{j=1}^{q} \alpha_j \mu_{\epsilon_j}(X) + \sum_{i=1}^{h} \beta_i \mu_{\delta_i}(X) \]  
\[ \sum_{j=1}^{q} \alpha_j + \sum_{i=1}^{h} \beta_i = 1, \; \alpha_j, \beta_i \geq 0 \]

where \( \alpha_j \) and \( \beta_i \) are the weighting coefficients that present the relative importance among the fuzzy goals and fuzzy constraints. The following crisp single objective programming is equivalent to the above fuzzy model:

\[ \text{Max} \sum_{j=1}^{q} \alpha_j \lambda_j + \sum_{i=1}^{h} \beta_i \gamma_i \]

Subject to:
\[ \lambda_j \leq \mu_{\epsilon_j}(x), \; j = 1, \& q \]
\[ \gamma_i \leq \mu_{\delta_i}(x), \; i = 1, \ldots, h \]
\[ g_p(x) \leq b_p, \; p = h+1, \ldots, m \]

3.3.1. Fuzzy Weights

To specify weights, there are some good approaches in the literature [13,17,28]. Here, Zenely’s maximin approach is discussed. Suppose that weights are described by linguistic variables which are given to describe membership grades for a set of all possible weight values. Then, the set of weights always adding up to one is obtained such that the minimal membership value is maximized.

\[ \text{Max } \min_{\mu_{\epsilon_i}}(a_i) \text{ Where } \sum a_i = 1 \]

For example, if there are three goals with associated weights \( a_1, a_2, \) and \( a_3 \), the optimal weight is obtained by solving the following problem:

\[ \text{Max } \min_{\mu_{\epsilon_i}}(a_i), \mu_{\delta_i}(a_2), \mu_{\delta_i}(a_3) \]

In the next part, we are going to present the proposed fuzzy multi objective supplier selection problem by numerical example.

4. Numerical Example

For supplying a new product to a market, assume that three suppliers should be managed. The purchasing criteria are net price, quality and service. The capacity constraints of suppliers are also considered. It is assumed that the input data from suppliers’ performance on these criteria are not known precisely. The de-fuzzified values of their cost, quality and service level and constraints of suppliers are presented in Table 1. The demand is a fuzzy number and is predicted to be about 1,000, as shown in Table 2.

<table>
<thead>
<tr>
<th>Supplier 1</th>
<th>Cost</th>
<th>Quality</th>
<th>Service</th>
<th>Capacity</th>
</tr>
</thead>
<tbody>
<tr>
<td>3</td>
<td>%85</td>
<td>%75</td>
<td></td>
<td>500</td>
</tr>
<tr>
<td>Supplier 2</td>
<td>2</td>
<td>%80</td>
<td>%90</td>
<td>600</td>
</tr>
<tr>
<td>Supplier 3</td>
<td>5</td>
<td>%95</td>
<td>%85</td>
<td>550</td>
</tr>
</tbody>
</table>

The fuzzified formulation of the numerical example is presented as:

\[ \tilde{Z}_1 = 3x_1 + 2x_3 + 5x_3 \leq Z_1^0 \]
\[ \tilde{Z}_2 = 0.85x_1 + 0.8x_2 + 0.95x_3 \leq Z_2^0 \]
\[ \tilde{Z}_3 = 0.75x_1 + 0.9x_2 + 0.85x_3 \leq Z_3^0 \]

Subject to:
\[ x_1 + x_2 + x_3 \approx 1000 \]
\[ x_1 \leq 500 \]
\[ x_2 \leq 600 \]
\[ x_3 \leq 550 \]
\[ x_i > 0, \; i=1,\ldots,3 \]

The linear membership function is used for fuzzifying the objective functions and demand constraint for the above problem according to (20), (21) and (22). The data set for the values of the lower bounds and upper bounds of the objective functions and a fuzzy number for the demand are given in Table 2.

<table>
<thead>
<tr>
<th>Tab. 2. The data set for membership functions</th>
</tr>
</thead>
<tbody>
<tr>
<td>( \mu = 0 )</td>
</tr>
<tr>
<td>( Z_1(\text{net cost}) )</td>
</tr>
<tr>
<td>( Z_2(\text{quality level}) )</td>
</tr>
<tr>
<td>( Z_3(\text{service level}) )</td>
</tr>
<tr>
<td>Demand</td>
</tr>
</tbody>
</table>

In Appendix A, the membership functions for three objectives and the demand constraint are provided by which to minimize the total monetary cost and maximize the total quality and service level of the purchased items. The fuzzy multi objective formulation for the example problem is as:

Find \( X \) to satisfy:
\[ \tilde{Z}_1 = 3x_1 + 2x_2 + 5x_3 \leq 2400 \]
\[ \tilde{Z}_2 = 0.85x_1 + 0.8x_2 + 0.95x_3 \leq 905 \]
\[ \tilde{Z}_3 = 0.75x_1 + 0.9x_2 + 0.85x_3 \leq 880 \]

subject to:
\[ x_1 + x_2 + x_3 \equiv 1000 \]
\[ x_1 \leq 500 \]
\[ x_2 \leq 600 \]
\[ x_3 \leq 550 \]
\[ x_i > 0, \quad i = 1, \ldots, 3 \]

\( \alpha_j \) (j = 1, 2, 3) and \( \beta_i \) are the weights associated with the jth objective and demand constraint. In this example the DMs relative importance or weights of the fuzzy goals are given vaguely as:
- important for cost objective, rather important for quality and service, and rather unimportant for demand constraint.
- The following information is also provided by DMs:

<table>
<thead>
<tr>
<th>Tab. 3. The value of weight membership functions</th>
</tr>
</thead>
<tbody>
<tr>
<td>( \alpha_j )</td>
</tr>
<tr>
<td>( \mu(\alpha_j) )</td>
</tr>
<tr>
<td>( \beta_i )</td>
</tr>
<tr>
<td>( \mu(\beta_i) )</td>
</tr>
<tr>
<td>( \mu(\beta_i) )</td>
</tr>
</tbody>
</table>

Then, we can use Equation (37) to get optimal weights. The result is \( \alpha_1 = 0.5, \alpha_2 = 0.2, \alpha_3 = 0.2 \), and the weight of the fuzzy constraint is \( \beta_1 = 0.1 \) with the membership grade = 0.7 = \( \min (0.8, 0.7, 0.7, 0.9) \).

Based on the convex fuzzy decision making (35)-(41) and the weights which are given by DMs, the crisp single objective formulation for the numerical example is as follows:

Max \( 0.5\lambda_1 + 0.2\lambda_2 + 0.2\lambda_3 + 0.1\gamma_1 \)

subject to:

\[ \lambda_1 \leq \frac{4100 - (3x_1 + 2x_2 + 5x_3)}{1700} \]
\[ \lambda_2 \leq \frac{(0.85x_1 + 0.8x_2 + 0.95x_3) - 820}{85} \]
\[ \lambda_3 \leq \frac{(0.75x_1 + 0.9x_2 + 0.85x_3) - 805}{75} \]
\[ \gamma_1 \leq \frac{1100 - (x_1 + x_2 + x_3)}{100} \]
\[ \gamma_1 \leq \frac{(x_1 + x_2 + x_3) - 950}{50} \]

\( X_1, X_2, X_3 \geq 0 \)

The linear programming software LINDO/LINGO is used to solve this problem. The optimal solution for the above formulation is obtained as follows:
\( X_1 = 400, X_2 = 600 \) and \( X_3 = 0 \)

\( \mu_{a_1}(x) = \lambda_1 = 1, \mu_{a_2}(x) = \lambda_2 = 0.95, \mu_{a_3}(x) = \lambda_3 = 0.466 \) and \( \gamma_1 = 1 \)

Corresponding to DMs preferences (0.2, 0.5, 0.2, 0.1), in this solution, 600(maximum capacity) items is assigned to be purchased from supplier 2, because of the lowest price and the remaining items are ordered to supplier 1.

If DMs relative importance or weights of cost criterion changes to rather important like as service and priority of quality changes to important, Table 4 presents this variation of DMs in cost and quality priority. Then, the order quantities vary as follows:
\( X_1 = 77, X_2 = 392 \) and \( X_3 = 550 \)

Corresponding to DMs preferences (0.2, 0.5, 0.2, 0.1), in this solution, 550(maximum capacity) items is assigned to be purchased from supplier 3, because of the highest quality level of supplier 3 performance on the quality criterion. The remaining items are split between supplier 2 and supplier 1.

In this case that variation in priority of criteria will cause variation in order quantities.

5. Summary and Conclusions

Supplier selection is one of the most important activities of purchasing departments. This importance is increased even more by new strategies in a supply chain, because of the key role suppliers perform in terms of quality, costs and services which affect the outcome in the buyer’s company. Supplier selection is a multiple criteria decision making problem in which the objectives are not equally important. In real cases, many input data are not known precisely for decision making. For the first time a fuzzy multi objective model is developed for supplier selection in order to assign different fuzzy weights to various criteria. Simultaneously, in this model, vagueness of input data...
and varying importance of criteria are considered. In real cases, where DMs face up to uncertain data and situations, the proposed model can help DMs to find out the appropriate ordering from each supplier, and allows purchasing manager(s) to manage supply chain performance on cost, quality, on time delivery, etc. Moreover, the fuzzy multi objective supplier selection problem transforms into a convex (weighted additive) fuzzy programming model and its equivalent crisp single objective LP programming. This transformation reduces the dimension of the system, giving less computational complexity, and makes the application of fuzzy methodology more understandable.

In a real situation, the proposed model can be implemented as a vector optimization problem; the basic concept is to use a single utility function to express the preference of DMs, in which the values of criteria and constraints are expressed in vague terms and are not equally important.
